Abstract

The SP_3 approximation of the neutron transport equation allows improving the accuracy for both static and transient simulations for reactor core analysis compared with the neutron diffusion theory. Besides, the SP_3 calculation costs are much less than higher order transport methods (S_N or P_N). Another advantage of the SP_3 approximation is a similar structure of equations that is used in the diffusion method. Therefore, there is no difficulty to implement the SP_3 solution option to the multi-group neutron diffusion codes.

In this paper, we attempt to employ a model reduction technique based on the multiscale method for neutron transport equation in SP_3 approximation. The proposed method is based on the use of a generalized multiscale finite element method (GMSFEM). The main idea is to create multiscale basis functions that can be used to effectively solve on a coarse grid. From calculation results, we obtain that multiscale basis functions can properly take into account the small-scale characteristics of the medium and provide accurate solutions. The application of the SP_3 methodology based on solution of the λ -spectral problems has been tested for the some reactor benchmarks. The results calculated with the GMSFEM are compared with the reference transport calculation results.

Keywords: neutron transport equation, SP_3 approximation, eigenvalues, multiscale simulation, generalized multiscale finite element method, GMSFEM

1. Introduction

2. Problem statement

Let us consider the symmetric form of the SP_3 equation for the neutron flux (?). The neutron dynamics is considered in the limited convex two-dimensional

or three-dimensional area Ω ($\mathbf{x} = \{x_1, \dots, x_d\} \in \Omega$, $d = 2, 3$) with boundary $\partial\Omega$. The neutron transport is described by the system of equations

$$\begin{aligned} & \frac{1}{v_g} \frac{\partial \phi_{0,g}}{\partial t} - \frac{2}{v_g} \frac{\partial \phi_{2,g}}{\partial t} - \nabla \cdot D_{0,g} \nabla \phi_{0,g} + \Sigma_{r,g} \phi_{0,g} - 2\Sigma_{r,g} \phi_{2,g} \\ & = (1 - \beta) \chi_{n,g} S_n + S_{s,g} + \chi_{d,g} S_d, \\ & - \frac{2}{v_g} \frac{\partial \phi_{0,g}}{\partial t} + \frac{9}{v_g} \frac{\partial \phi_{2,g}}{\partial t} - \nabla \cdot D_{2,g} \nabla \phi_{2,g} + 5\Sigma_{t,g} + 4\Sigma_{r,g} \phi_{2,g} - 2\Sigma_{r,g} \phi_{0,g} \\ & = -2(1 - \beta) \chi_{n,g} S_n - 2S_{s,g} - 2\chi_{d,g} S_d, \end{aligned} \quad (1)$$

where

$$\begin{aligned} S_n &= \sum_{g'=1}^G \nu \Sigma_{f,g'} \phi_{g'}, \quad S_{s,g} = \sum_{g \neq g'=1}^G \Sigma_{s,g' \rightarrow g} \phi_{g'}, \quad S_d = \sum_{m=1}^M \lambda_m c_m, \\ \phi_{0,g} &= \phi_g + 2\phi_{2,g}, \quad D_{0,g} = \frac{1}{3\Sigma_{tr,g}}, \quad D_{2,g} = \frac{9}{7\Sigma_{t,g}}, \quad g = 1, 2, \dots, G. \end{aligned}$$

Here G — number of energy groups, $\phi_g(\mathbf{x}, t)$ — scalar flux, $\phi_{0,g}(\mathbf{x}, t)$ — pseudo 0th moment of angular flux, $\phi_{2,g}(\mathbf{x}, t)$ — second moment of angular flux, $\Sigma_{t,g}(\mathbf{x}, t)$ — total cross-section, $\Sigma_{tr,g}(\mathbf{x}, t)$ — transport cross-section, $\Sigma_{r,g}(\mathbf{x}, t)$ — removal cross-section, $\Sigma_{s,g' \rightarrow g}(\mathbf{x}, t)$ — scattering cross-section, χ_g — spectra of neutrons, $\nu \Sigma_{f,g}(\mathbf{x}, t)$ — generation cross-section, $c_m(\mathbf{x}, t)$ — density of sources of delayed neutrons, λ_m — decay constant of sources of delayed neutrons, M — number of types of delayed neutrons.

The density of sources of delayed neutrons is described by the equations

$$\frac{\partial c_m}{\partial t} + \lambda_m c_m = \beta_m S_n, \quad m = 1, 2, \dots, M, \quad (2)$$

where β_m is the fraction of delayed neutrons of m -type, and

$$\beta = \sum_{m=1}^M \beta_m.$$

The Marshak-type conditions are set at the boundary of the area $\partial\Omega$

$$\begin{aligned} \begin{bmatrix} J_{0,g}(\mathbf{x}) \\ J_{2,g}(\mathbf{x}) \end{bmatrix} &= \begin{bmatrix} \frac{1}{2} & -\frac{3}{8} \\ -\frac{3}{8} & \frac{21}{8} \end{bmatrix} \begin{bmatrix} \phi_{0,g}(\mathbf{x}) \\ \phi_{2,g}(\mathbf{x}) \end{bmatrix}, \\ J_{i,g}(\mathbf{x}) &= -D_{i,g} \nabla \phi_{i,g}(\mathbf{x}), \quad i = 0, 2. \end{aligned} \quad (3)$$

System of equations (1) and (2) is supplemented with boundary conditions (3) and corresponding initial conditions

$$\begin{aligned} \phi_g(\mathbf{x}, 0) &= \phi_g^0(\mathbf{x}), \quad g = 1, 2, \dots, G, \\ c_m(\mathbf{x}, 0) &= c_m^0(\mathbf{x}), \quad m = 1, 2, \dots, M. \end{aligned} \quad (4)$$

We assume that at the initial time $t = 0$, the reactor is in steady-state critical condition.

Discretization. Define a uniform grid

$$\omega = \{t^n = n\tau, \quad n = 0, 1, \dots, N, \quad \tau N = T\}$$

and use the next notations $\phi_g^n = \phi_g(\mathbf{x}, t^n)$, $c_m^n = c_m(\mathbf{x}, t^n)$. We discretize the time derivatives of equation (1) using finite-difference scheme. For approximation in time, we use a fully implicit scheme with time step τ . For delayed neutron source equation we use numerical-analytical method for the construction of approximations in time. The equation (2) in the equivalent form

$$\frac{\partial e^{\lambda_m t} c_m}{\partial t} = \beta_m e^{\lambda_m t} \sum_{g=1}^G \nu \Sigma_{fg} \phi_g, \quad m = 1, 2, \dots, M.$$

After integration on time interval $[t^n, t^{n+1}]$ one can obtain

$$c_m^{n+1} = e^{-\lambda_m \tau} c_m^n + \beta_m \int_{t_n}^{t_{n+1}} e^{\lambda_m(t-t^{n+1})} \sum_{g=1}^G \nu \Sigma_{fg} \phi_g dt, \quad m = 1, 2, \dots, M. \quad (5)$$

For spatial approximation we use the finite element method. Let $H^1(\Omega)$ – Sobolev space, $q \in H^1$: q^2 and $|\nabla q|^2$ have a finite integral in Ω . Using the integration by parts, we obtain the following variational formulation: let's find $\phi_g^{n+1} \in V^G$ such that

$$\begin{aligned} & \int_{\Omega} \left(\frac{\phi_{0,g}^{n+1} - \phi_{0,g}^n}{v_g \tau} - \frac{2(\phi_{2,g}^{n+1} - \phi_{2,g}^n)}{v_g \tau} \right) q_g d\mathbf{x} - \int_{\Omega} D_{0,g} \nabla \phi_{0,g}^{n+1} \nabla q_g d\mathbf{x} \\ & + \int_{\partial\Omega} J_{0,g}^{n+1} q_g d\mathbf{s} + \int_{\Omega} (\Sigma_{r,g} \phi_{0,g}^{n+1} - 2\Sigma_{r,g} \phi_{2,g}^{n+1}) q_g d\mathbf{x} \\ & = \int_{\Omega} ((1 - \beta) \chi_{n,g} S_n^{n+1} + S_{s,g}^{n+1} + \chi_{d,g} S_d^{n+1}) q_g d\mathbf{x}, \\ & \int_{\Omega} \left(-\frac{2(\phi_{0,g}^{n+1} - \phi_{0,g}^n)}{v_g \tau} + \frac{9(\phi_{2,g}^{n+1} - \phi_{2,g}^n)}{v_g \tau} \right) q_g d\mathbf{x} - \int_{\Omega} D_{2,g} \nabla \phi_{2,g}^{n+1} \nabla q_g d\mathbf{x} \\ & + \int_{\partial\Omega} J_{2,g}^{n+1} q_g d\mathbf{s} + \int_{\Omega} ((5\Sigma_{t,g} + 4\Sigma_{r,g}) \phi_{2,g}^{n+1} - 2\Sigma_{r,g} \phi_{0,g}^{n+1}) q_g d\mathbf{x} \\ & = \int_{\Omega} (-2(1 - \beta) \chi_{n,g} S_n^{n+1} - 2S_{s,g}^{n+1} - 2\chi_{d,g} S_d^{n+1}) q_g d\mathbf{x}, \end{aligned} \quad (6)$$

where $V^G = [H^1(\Omega)]^G$.

Further, it's necessary to pass from the continuous variational problem (6) to the discrete problem. We introduce finite-dimensional space of finite elements $V_h^G \subset V^G$ and formulate a discrete variational problem. We use standard linear basis functions as basis functions to solve the problem on the fine grid. The problem is solving a system of linear algebraic equations

$$A_f \phi = b_f, \quad (7)$$

where the operator A_f corresponds to the bilinear form of equation, and the vector b_f corresponds to the linear form of equation (6).

3. Multiscale method

For the discretization on the coarse grid we use GMsFEM. We construct two grids: fine grid (\mathcal{T}_h) and coarse grid (\mathcal{T}_H) (see Figure 1). For multiscale basis construction, we define local domains ω_i , where $i = 1, \dots, N_v$ and N_v is the number of coarse grid nodes. We assume that \mathcal{T}_h is a refinement of \mathcal{T}_H , where h and H represent the fine and coarse grid sizes, respectively. We assume that the fine-scale grid \mathcal{T}_h is sufficiently fine to fully resolve the small-scale information of the domain while \mathcal{T}_H is a coarse grid containing many fine-scale features. A local domain ω_i is obtained by the combining all the coarse cells around one vertex of the coarse grid.

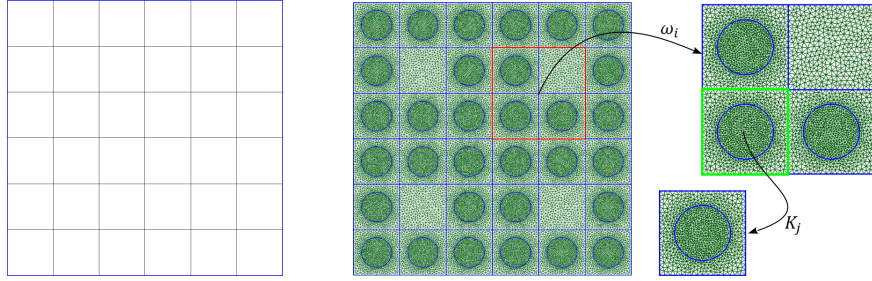

Figure 1: Coarse grid and local domain ω_i with K_j

We construct the multiscale function spaces

$$V_{\text{off}} = \text{span}\{y_j\}_{j=1}^N,$$

where N is the number of coarse basis functions. Each y_j is supported in local domain ω_i .

Basis functions are designed to capture the multiscale features of the solution. Important multiscale features of the solution are incorporated into localized basis functions which contain information about the scales that are smaller (as well as larger) than the local numerical scale defined by the basis functions.

Multiscale space. The computation of basis functions use local spectral problems to reduce the dimension of the local problem. In order to construct conforming basis functions, we multiply eigenvectors related to dominant eigenvalues to the partition of unity functions. We use following spectral problem in ω_i

$$A\varphi^i = \lambda S\varphi^i, \quad (8)$$

where the elements of the matrices $A = \{a_{ij}\}$ and $S = \{s_{ij}\}$ are defined as

follow

$$\begin{aligned} a_{ij} &= \int_{\omega_i} \\ s_{ij} &= \int_{\omega_i} \end{aligned} \quad (9)$$

Then, we choose eigenvectors corresponding to dominant M_i eigenvalues from (6) and use them to construct the multiscale basis functions.

As partition of unity functions, we use linear functions in each domain ω_i . Partitions of unity are calculated in the domain K_j as a linear function from Γ to the vertex A , and 0 is assigned to the entire segment Γ , and at point A is assigned the value 1. Thus, we obtain a linear function from 0 to 1 over the entire domain K_j . Partitions of unity are shown in Figure 2. Domain K_j is one element from a coarse grid.

Figure 2: Partition of unity functions on the ω_i (right) and K_j (left)

The multiscale space is defined as the span of $y_i = \chi_i \varphi_k^i$, where χ_i is the usual nodal basis function for the node i (linear partition of unity functions). The number of bases can be different, the accuracy of the solution can be improved when we increase the number of bases.

Coarse-scale approximation. Next, we create the following matrix for each ω_i

$$R^i = [y_1, \dots, y_{M_i-1}, y_{M_i}].$$

and define the transition matrix R (transition from a fine grid to a coarse grid) to reduce the dimension of the problem

$$R = [R^1, R^2, \dots, R^{N_v}],$$

where N_v is the number of local domains ω_i .

Then using the transition matrix R and fine grid system (5), we construct the coarse grid approximation

$$A_c \phi_c = b_c, \quad A_c = R A_f R^T \quad \text{and} \quad b_c = R b_f, \quad (10)$$

and using the coarse-scale solution ϕ_c , we can reconstruct the fine grid solution

$$\phi_{ms} = R^T \phi_c.$$

4. Numerical results

4.1. One group heterogeneous test

Let's consider the 2D test problem for small PWR reactor (Ω — reactor core area). The geometrical model of the small PWR reactor core is presented in Fig.3. The diameter of the fuel rods is 0.82 cm, the cell width is 1.26 cm. Diffusion neutronics constants in the common notations are given in Table 1. There are two types of cassettes, with fuel 1% UO_2 and 2% UO_2 . The reflective boundary conditions (2) are used ($\gamma = 0$). The following delayed neutrons parameters are used: $\beta = 6.5 \cdot 10^{-3}$, $\lambda = 0.08 \text{ s}^{-1}$ and $v = 5 \cdot 10^5 \text{ cm/s}$.

Figure 3: Geometrical model of the small PWR-2D reactor core

We define the next scenario of the process:

- The λ -spectral problem is solved and the solution is taken as the initial condition;
- Calculation for the non-stationary model at the time range from 0 to 0.4 sec;
- At $t = 0.1 \text{ sec}$ and $t = 0.3 \text{ sec}$ Σ_a for fuel in the zone 1 changes to +2% and -3%, respectively (simulation of insertion or withdrawal of control rods).

At each time the integrated power is calculated as

$$P(t) = a \int_{\Omega} \Sigma_f \phi d\mathbf{x},$$

Table 1: Neutronics constants for small PWR-2D.

	1		2	
	coolant	fuel	coolant	fuel
D	0.34473872	0.77002585	0.31679441	0.80236505

ν	0.0	2.44844862	0.0	2.45482762

where a is the normalization coefficient, which corresponds to a given value of the integrated power.

The coarse grid contains 49 vertices. The fine grid contains 115891 vertices. The time step for both grids is $\tau = 0.001$. As an exact solution, we take the fine-grid solution. The initial value of K_{eff} is 1.xxxxxx.

Figure 4: Geometrical model of 1/4 reactor core TWIGL-2D.

5. Conclusions

A Generalized Multiscale Finite Element method was developed successfully for modelling neutron transport in one-group SP_3 approximation. We presented an implementation of GMSFEM. We considered each step of GMSFEM algorithm. The results showed that GMSFEM performed with a good accuracy in all considered cases.

In the current work, we considered a popular and simple model of neutron transport equation. Computational expenses are always an issue even for modern computers. In the future, we will consider more complex models of neutron transport, such as P_N approximation.
