## Abstract

In this paper, we attempt to employ a model reduction technique based on the multiscale method for neutron diffusion equation. The neutron diffusion approximation is widely used for reactor analysis and applied in most engineering calculation codes. The proposed method is based on the use of a generalized multiscale finite element method. The main idea is to create multiscale basis functions that can be used to effectively solve on a coarse grid. From calculation results, we obtain that multiscale basis functions can properly take into account the small-scale characteristics of the medium and provide accurate solutions.

**Keywords:** parabolic equation, neutron diffusion, multiscale simulation, generalized multiscale finite element method (GMsFEM)

## 1 Introduction

Among the basic physical processes occurring in a nuclear reactor [1], the focus is on neutron transport. To predict the neutron distribution, a rather complex integro-differential equation is involved; besides, the neutron flux distribution depends on time, energy, spatial and angular variables [2]. In practical calculations of nuclear reactors, as a rule, different approximative forms of the neutron transport equation are used. For example, the most neutronics codes are based on the multigroup diffusion equations. The computational model is a system of

coupled second-order parabolic equations, which is supplemented by a system of ordinary differential equations to take into account delayed neutrons.

The stationary state of neutron flux, which is related to the critical state of the reactor, is characterised by local balancing of neutron absorption and generation. This boundary state is usually described by solution of a spectral problem (Lambda Modes problem [3–5]) provided that the fundamental eigenvalue (maximal eigenvalue) that is called  $k$ -effective of the reactor core, is equal to unity. In this case, the stationary neutron field is related with the corresponding eigenfunction. Computations of  $k$ -effective of the reactor using the Lambda Modes problem are obligatory for reactor design calculations.

Real dynamic neutronic calculations require the use of large computational grids during large characteristic times. For these reasons, the reactor calculations can be very expensive. When solving these problems, it is common to use numerical averaging techniques or different multiscale methods that can significantly reduce the number of unknowns, through the construction of coarse-scale model. Also note a class of methods for modelling the non-stationary neutron diffusion, which is associated with the multiplicative representation of the space-time factorization methods and the quasistatic method [6, 7]. The general strategy for the approximate solution of the non-stationary problems of neutron transport, which is oriented to fast calculations using the state change modal method was formulated in [8].

Homogenization methods are used for coarse-grid approximation and allow calculating the effective properties of the domain. As a result, the methods of numerical homogenization establish macroscopic laws on the basis of local computations, but such approaches are usually based on a priori formulated assumptions, see e.g. [9–11]. On the other hand, multiscale methods construct multiscale basis functions in each coarse-grid block and couple these basis functions in a global formulation. These methods have a two-way information exchange between micro- and macro-scales. There are many variations of multiscale finite element methods (MsFEM). A detailed description of several variations of the method is presented in [12].

In this paper, we propose a Generalized Multiscale Finite Element Method (GMsFEM [13, 14]) to solve the neutron diffusion equation. The main idea of the GMsFEM is the dimensionality reduction of the problem. GMsFEM involves two basic steps: the construction of multiscale basis functions that take into account small scale heterogeneities in local domains and the construction of the coarse scale approximation. For the construction of the multiscale basis functions we solve spectral problems in local domains. Spectral problems allow identifying the most important characteristics of the solution. In contrast to the available techniques, this method allows to avoid the limitations associated with idealization and the applicability of the method. This method also more general technology that takes into account the different scale processes. The construction of basis functions occurs independently for each local domain and doesn't require information exchanges between processors, and the method is effective in a high parallelization. Using constructed multiscale basis functions, we construct a mathematical model on a coarse grid that allows to significant

reduce the solution time, the amount of used memory, and can be used to perform calculations for a given configuration of heterogeneous properties.

In this paper, we present numerical results for 2D small PWR test. We compare the GMsFEM results with the fine-grid simulations. In these calculations, we use various number of multiscale basis functions in each local subdomain. As can be seen, as the number of basis functions increases, the multiscale solution becomes more accurate. In particular, when we use few functions, the result is not accurate, therefore it necessary to select more basis functions. The errors of the method are shown in  $L_2$  and  $H_1$  norms.

## 2 Problem statement

Let's consider a one-group diffusion approximation for the neutron transport modelling. We consider a bounded 2D domain  $\Omega$  ( $\mathbf{x} = \{x_1, x_2\} \in \Omega$ ) with a convex boundary  $\partial\Omega$ . The one-group transport equation in the diffusion approximation with one-group delayed neutron source can be written as follows:

$$\begin{aligned} \frac{1}{v} \frac{\partial \phi}{\partial t} - \nabla \cdot D \nabla \phi + \Sigma_r \phi &= \frac{1 - \beta}{K_{eff}} \nu \Sigma_f \phi + \lambda c, \\ \frac{\partial c}{\partial t} + \lambda c &= \frac{\beta}{K_{eff}} \nu \Sigma_f \phi. \end{aligned} \quad (1)$$

Here  $\phi(\mathbf{x}, t)$  is the neutron flux at point  $\mathbf{x}$  and time  $t$ ,  $c(\mathbf{x}, t)$  is density of sources of delayed neutrons,  $v$  is the effective neutron velocity,  $D(\mathbf{x}, t)$  is the diffusion coefficient,  $\Sigma_r(\mathbf{x}, t)$  is the removal cross-section,  $\Sigma_f(\mathbf{x}, t)$  is the fission cross-section,  $\beta$  is the effective fraction of delayed neutrons,  $\lambda$  is the decay constant of the delayed neutron source.

Let's determine the boundary and initial conditions for Equation (1). The albedo-type conditions are set at the boundary  $\partial\Omega$ :

$$D \frac{\partial \phi}{\partial n} + \gamma \phi = 0, \quad (2)$$

where  $n$  is an outer normal to the boundary  $\partial\Omega$ ,  $\gamma$  is the albedo constant.

Let's propose that at the initial time  $t = 0$ , the reactor is in steady-state critical condition

$$\phi(\mathbf{x}, 0) = \phi^0(\mathbf{x}). \quad (3)$$

To solve the problem within the domain  $\Omega$ , we approximate the system of equations (1)-(3) using the finite element method [15]. We discretize the time derivatives using finite-difference scheme, and then bring each stationary problem to a variational formulation. For approximation in time, we use a fully implicit scheme with time step  $\tau$ . To specify the variational formulation, we multiply equations by the test function  $q$  and integrate over the domain  $\Omega$ . Using the integration by parts, we obtain the following variational formulation: let's find

$\phi^{n+1} \in V$  such that

$$\begin{aligned} \int_{\Omega} \frac{1}{v} \frac{\phi^{n+1}}{\tau} q d\mathbf{x} + \int_{\Omega} D^{n+1} \nabla \phi^{n+1} \cdot \nabla q d\mathbf{x} + \int_{\Omega} \Sigma_r^{n+1} \phi^{n+1} q d\mathbf{x} - \\ \int_{\Omega} \frac{1 + \lambda\tau - \beta}{K_{eff}(1 + \lambda\tau)} \nu \Sigma_f^{n+1} \phi^{n+1} q d\mathbf{x} + \int_{\partial\Omega} \gamma \phi^{n+1} q ds = \\ \int_{\Omega} \frac{1}{v} \frac{\phi^n}{\tau} q d\mathbf{x} + \int_{\Omega} \frac{\lambda c^n}{1 + \lambda\tau} q d\mathbf{x}, \quad \forall q \in V, \end{aligned} \quad (4)$$

where  $V = H^1(\Omega)$  is the Sobolev space consisting of scalar functions  $v$  such that  $v^2$  and  $|\nabla v^2|$  have a finite integral in  $\Omega$ .

Further, it's necessary to pass from the continuous variational problem (4) to the discrete problem. We introduce finite-dimensional space of finite elements  $V_h \subset V$  and formulate a discrete variational problem. We use standard linear basis functions as basis functions to solve the problem on the fine grid and

$$\phi = \sum_{i=1}^{N_f} \phi_i y_i,$$

where  $N_f$  is the number of vertices on the fine grid.

The problem is solving a system of linear algebraic equations

$$A_f \phi = b_f, \quad (5)$$

where the operator  $A_f$  corresponds to the left side of equation (4), and the vector  $b_f$  corresponds to the right side of equation (4).

### 3 Multiscale method

For the discretization on the coarse grid we use GMsFEM. We construct two grids: fine grid ( $\mathcal{T}_h$ ) and coarse grid ( $\mathcal{T}_H$ ) (see Figure 1). For multiscale basis construction, we define local domains  $\omega_i$ , where  $i = 1, \dots, N_v$  and  $N_v$  is the number of coarse grid nodes. We assume that  $\mathcal{T}_h$  is a refinement of  $\mathcal{T}_H$ , where  $h$  and  $H$  represent the fine and coarse grid sizes, respectively. We assume that the fine-scale grid  $\mathcal{T}_h$  is sufficiently fine to fully resolve the small-scale information of the domain while  $\mathcal{T}_H$  is a coarse grid containing many fine-scale features. A local domain  $\omega_i$  is obtained by the combining all the coarse cells around one vertex of the coarse grid.

We construct the multiscale function space

$$V_{\text{off}} = \text{span}\{y_j\}_{j=1}^N,$$

where  $N$  is the number of coarse basis functions. Each  $y_j$  is supported in local domain  $\omega_i$ .

Basis functions are designed to capture the multiscale features of the solution. Important multiscale features of the solution are incorporated into localized basis functions which contain information about the scales that are smaller (as well as larger) than the local numerical scale defined by the basis functions.

Figure 1: Coarse grid and local domain  $\omega_i$  with  $K_j$

**Multiscale space.** The computation of basis functions use local spectral problems to reduce the dimension of the local problem. In order to construct conforming basis functions, we multiply eigenvectors related to dominant eigenvalues to the partition of unity functions. We use following spectral problem in  $\omega_i$

$$A\varphi^i = \lambda S\varphi^i, \quad (6)$$

where the elements of the matrices  $A = \{a_{ij}\}$  and  $S = \{s_{ij}\}$  are defined as follow

$$\begin{aligned} a_{ij} &= \int_{\omega_i} D\nabla\phi \cdot \nabla q d\mathbf{x} + \int_{\omega_i} \Sigma_r \phi q d\mathbf{x} - \int_{\omega_i} \frac{1 + \lambda\tau - \beta}{K_{eff}(1 + \lambda\tau)} \nu \Sigma_f \phi q d\mathbf{x}, \\ s_{ij} &= \int_{\omega_i} D u q d\mathbf{x}. \end{aligned} \quad (7)$$

Then, we choose eigenvectors corresponding to dominant  $M_i$  eigenvalues from (6) and use them to construct the multiscale basis functions.

**Partition of unity functions.** As partition of unity functions, we use linear functions in each domain  $\omega_i$ . Partitions of unity are calculated in the domain  $K_j$  as a linear function from  $\Gamma$  to the vertex  $A$ , and 0 is assigned to the entire segment  $\Gamma$ , and at point  $A$  is assigned the value 1. Thus, we obtain a linear function from 0 to 1 over the entire domain  $K_j$ . Partitions of unity are shown in Figure 2. Domain  $K_j$  is one element from a coarse grid.

The multiscale space is defined as the span of  $y_i = \chi_i \varphi_k^i$ , where  $\chi_i$  is the usual nodal basis function for the node  $i$  (linear partition of unity functions). The number of bases can be different, the accuracy of the solution can be improved when we increase the number of bases.

**Coarse-scale approximation.** Next, we create the following matrix for each  $\omega_i$

$$R^i = [y_1, \dots, y_{M_i-1}, y_{M_i}].$$

and define the transition matrix  $R$  (transition from a fine grid to a coarse grid) to reduce the dimension of the problem

$$R = [R^1, R^2, \dots, R^{N_v}],$$

Figure 2: Partition of unity functions on the  $\omega_i$  (right) and  $K_j$  (left)

where  $N_v$  is the number of local domains  $\omega_i$ .

Then using the transition matrix  $R$  and fine grid system (5), we construct the coarse grid approximation

$$A_c \phi_c = b_c, \quad A_c = R A_f R^T \quad \text{and} \quad b_c = R b_f, \quad (8)$$

and using the coarse-scale solution  $\phi_c$ , we can reconstruct the fine grid solution

$$\phi_{ms} = R^T \phi_c.$$

## 4 Numerical results

Let's consider the 2D test problem for small PWR reactor ( $\Omega$  — reactor core area). The geometrical model of the small PWR reactor core is presented in Fig.3. The diameter of the fuel rods is 0.82 cm, the cell width is 1.26 cm. Diffusion neutronics constants in the common notations are given in Table 1. There are two types of cassettes, with fuel 1%  $UO_2$  and 2%  $UO_2$ . The reflective boundary conditions (2) are used ( $\gamma = 0$ ). The following delayed neutrons parameters are used:  $\beta = 6.5 \cdot 10^{-3}$ ,  $\lambda = 0.08 \text{ s}^{-1}$  and  $v = 5 \cdot 10^5 \text{ cm/s}$ .

We define the next scenario of the process:

- The  $\lambda$ -spectral problem is solved and the solution is taken as the initial condition;
- Calculation for the non-stationary model at the time range from 0 to 0.4 sec;
- At  $t = 0.1 \text{ sec}$  and  $t = 0.3 \text{ sec}$   $\Sigma_a$  for fuel in the zone 1 changes to +2% and -3%, respectively (simulation of insertion or withdrawal of control rods).

At each time the integrated power is calculated as

$$P(t) = a \int_{\Omega} \Sigma_f \phi d\mathbf{x},$$

Figure 3: Geometrical model of the small PWR-2D reactor core

where  $a$  is the normalization coefficient, which corresponds to a given value of the integrated power.

Table 1: Diffusion neutronics constants for the small PWR-2D reactor core

Zone	1		2	
	coolant	fuel	coolant	fuel
$D$	0.34473872445	0.77002585054	0.31679441560	0.80236505122
$\Sigma_a$	5.3858400E-03	8.9337900E-02	6.0670900E-03	6.6279500E-02
$\Sigma_f$	0.0	5.4731800E-02	0.0	3.3377700E-02
$\nu$	0.0	2.44844861671	0.0	2.45482762443

The coarse grid contains 49 vertices. The fine grid contains 115891 vertices. The time step for both grids is  $\tau = 0.001$ . As an exact solution, we take the fine-grid solution. The initial value of  $K_{eff}$  is 1.183280.

The integral power for the fine grid and relative errors of integral powers are shown in Figure 4. When using single basis, the error does not exceed 1%, and for using 4 or more bases it does not exceed 0.01%.

In Figure 5, we present relative  $L_2$  and  $H_1$  errors of the multiscale solution vs. time for different number of multiscale basis functions. The numerical results show good convergence behaviour, provided that we take sufficient number of the multiscale basis functions.

In Table 2, we present relative  $L_2$  and  $H_1$  errors at final time for different number of the multiscale basis functions. For example, when we use 8 spectral basis functions, we obtain 0.34% for  $L_2$  error and 7.18% for  $H_1$  error. Our calculations show that it is necessary to use 4 or more basis functions. In

Figure 4: Integral power (the fine grid) and relative errors (%) of the multiscale solution power.

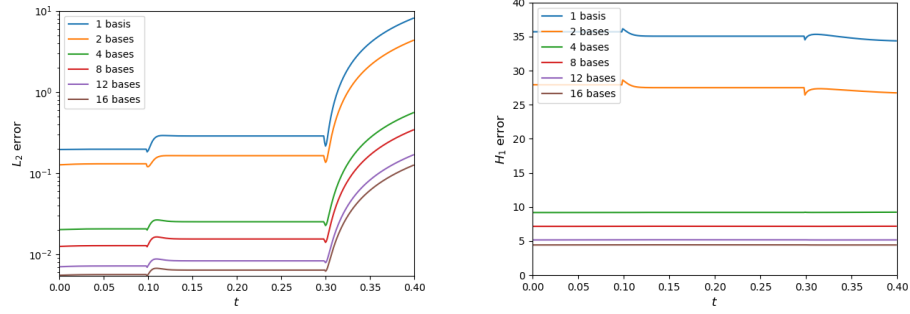

Figure 5: Relative  $L_2$  and  $H_1$  errors (%) of the multiscale solution.

Figure 6, we present first four (of 16) multiscale basis functions in local domain  $\omega_i$ . The fine-grid solution and the multiscale solution (16 basis functions on each local domain)  $\omega_i$  are shown in Figure 7. Relative errors are 0.13% for  $L_2$  and 4.43% for  $H_1$ .

Table 2: Relative  $L_2$  and  $H_1$  errors (%) of the solution at final time.

## 5 Conclusions

A Generalized Multiscale Finite Element method was developed successfully for modelling neutron transport in one-group diffusion approximation. We presented an implementation of GMsFEM. We considered each step of GMsFEM algorithm. The results showed that GMsFEM performed with a good accuracy in all considered cases.

In the current work, we considered the most popular and simplest model of neutron transport equation. Computational expenses are always an issue even for modern computers. In the future, we will consider more complex models of neutron transport, such as  $SP_3$  approximation.
